

CHAPTER – II

IDEATION PHASE

2.1 – Problem Statement

Agriculture is one of the most important sectors of India's economy, providing food security, employment, and raw materials for various industries. However, agricultural crop production varies significantly across different states and years due to factors such as climate change, rainfall patterns, soil conditions, irrigation facilities, and farming practices.

The large volume of agricultural data makes it difficult to identify production trends, compare crop performance, and make informed decisions. Farmers, policymakers, and researchers often face challenges in understanding which crops perform better in specific regions and how production has changed over time.

The main problem is the lack of a clear, visual, and data-driven analysis of India's agricultural crop production. Without proper analysis, it becomes difficult to improve productivity, optimize resource allocation, and support sustainable agricultural development.

This project aims to analyze agricultural crop production data using data visualization techniques to identify trends, compare state-wise and crop-wise production, evaluate yield patterns, and provide meaningful insights that can assist in better agricultural planning and decision-making.

summary:

The main problem is the absence of an integrated and interactive system to efficiently analyze India's agricultural crop production data, resulting in difficulties in identifying trends, regional variations, and opportunities for better agricultural planning and policy-making.
